#### Chap 13. Continuous functions on a compact intervals

#### 13.1 Compact intervals

The principal goal is to prove three important local-to-global type theorems:

If f(x) is **continuous** on any <u>finite closed</u> (= closed and bounded) interval I, then on I 구간의 생기가 무한이 될 수 없는

- (i) f(x) is bounded
- (ii) f(x) has a maximum and minimum
- (iii) f(x) is uniformly continuous (the notion of uniform continuity will be introduced in section 13.5)

면속성이란 local property 인데, 위 3퇴용 global property OICT.

Note: Continuity (on I) is a local property but (i), (ii), & (iii) (i.e., boundedness,

maximum (minimum) property, and uniform continuity on I) are global properties.

From now on, we call a <u>finite closed</u> (= closed and bounded) interval [a, b] a **compact** interval.

Such intervals alone have the property called "sequential compactness"

→ S 안에 어떤 점으로 수형하는 임의의 부분수ছ을 택할 수 있다면 sequentially compact of CLZ of CL

Def. A set  $S \subseteq \mathbb{R}$  is said to be sequentially compact if every sequence of points in S has a subsequence converging to a point in S. (i.e.,  $\forall$  sequence  $(x_n)$  in S,  $\exists$  a convergent subsequence  $(x_n)$  such that  $\lim x_n \in S$ 

#### **Sequential Compactness Theorem (SCT)** Theorem

A compact interval [a, b] is sequentially compact

Pf. Let  $\{x_n\}$  be any seq in [a,b]. Then it is bounded since the interval is finite.

By BWT, it has a convergent subsequence  $\left\{x_{n_i}\right\}$ ; set  $\lim_{i \to \infty} x_{n_i} = c$ 

$$(---$$
 boundedness of  $[a,b]$  is used  $---$ )

Since every 
$$x_n \in [a,b]$$
, we have in particular  $\underline{a} \leq x_{n_i} \leq b$  for all  $i$  Thus, by LLT (or by taking limits), 
$$(a,b], [a,b), (a,b), (a,b),$$

Therefore, [a, b] is sequentially compact

Sequential Compactness 7+ 43512 SECH

Remark. recall the different types of intervals:

$$[a,b]$$
: finite closed i.e., compact

$$[a, \infty), (-\infty, a]$$
: semi-infinite closed

(a,b): finite open

$$(a, \infty), (-\infty, a)$$
: semi-infinite open

(a,b], [a,b): finite half-open

$$(-\infty, \infty) = \mathbb{R}$$
: infinite open and closed

not compact

For example,

 $[a,\infty)$  (or  $(a,\infty)$ ) contains the sequence  $\{n\}_{n_0}^{\infty}$  (with  $n_0>a$ ), which has no convergent

subsequence  $I=(a,b] \text{ (or } (a,b)) \text{ contains a tail of the seq } \left\{a+\frac{1}{n}\right\}_{n_0}^{\infty}, \text{ which converges to the point } a\not\in I.$ 

 $\therefore$  any subsequence of  $\left\{a+\frac{1}{n}\right\}_{n=1}^{\infty}$  also converges to  $a \notin I$ , by the Subsequence Theorem.

$$[a,b): \ {\rm consider} \ \left\{b-\frac{1}{n}\right\}_{n_0}^{\infty}$$

# 13.2 Bounded continuous functions

# **Theorem (Boundedness Theorem)**

If f(x) is continuous on a compact interval I, then f(x) is bounded on IPf. Suppose f(x) is not bounded on I. Then

f(x) is not bounded above on I or f(x) is not bounded below on I.

Suppose first that f(x) is not bounded above on I. Then

$$\exists \ x_1 \in \mathbf{I} \quad \text{s.t.} \quad f(x_1) > 1$$
 
$$\exists \ x_2 \in \mathbf{I} \quad \text{s.t.} \quad f(x_2) > 2$$
 
$$\vdots$$
 
$$\exists \ x_n \in \mathbf{I} \quad \text{s.t.} \quad f(x_n) > n$$
 
$$\vdots$$
 That is, 
$$\exists \quad \mathbf{a} \ \text{seq} \ \{x_n\}_1^\infty \quad \text{in} \ \mathbf{I} \ \text{s.t.} \ f(x_n) > n$$

 $\{x_n\}_{n=1}^{\infty}$  is a seq in the compact interval  $I \stackrel{\text{SCT}}{\Rightarrow} \exists$  a subseq  $\{x_{n_i}\}$  converging to a point  $c \in I$ :

$$\lim_{i o \infty} x_{n_i} = c$$
, where  $c \in \mathbf{I}$   $\sim$   $\chi_{n_i}$  가 C로 설렜야 하지만

We note first that, since  $f(x_{n_i}) > n_i$ ,

$$\lim_{i \to \infty} f(x_{n_i}) \ge \lim_{i \to \infty} n_i = \infty \qquad i.e., \ \lim_{i \to \infty} f(x_{n_i}) = \infty$$

But since f is contiat  $c \in I$  and  $\lim_{i \to \infty} x_{n_i} = c$ ,

$$\lim_{i \to \infty} f(x_{n_i}) = f(c) \quad \text{(by Sequential Continuity Theorem)}$$

This leads to a contradiction, since  $c \in I$  implies that f(c) is definite and finite

f(x) must be bounded above

To show that f(x) is also bounded below, we note that

-f(x) is conti on the compact interval I

the above result  $\Rightarrow$  -f(x) is bounded above on I i.e., -f(x) < K for all  $x \in I$   $\Rightarrow$  f(x) > -K for all  $x \in I$ 

 $\therefore$  f(x) is bounded below on I

Remark. The conclusion in the Boundedness theorem would be <u>false</u> if "compact" were omitted. For example,

$$f(x) = \frac{1}{x}$$
 is conti on  $\ (0,1]$  but it is not bounded there

Or

f(x) = x is conti on  $[0, \infty)$  but it is not bounded there

#### 13.3 Extremal points of continuous functions

### Theorem Maximum-Minimum theorem (최대-최소 정리)

Let f(x) be continuous on the compact interval I. Then  $\exists \overline{x}, \underline{x} \in I$  such that

$$f(\overline{x}) = \sup_{x \in I} f(x), \qquad f(\underline{x}) = \inf_{x \in I} f(x)$$

i.e., every contift f(x) has a maximum and minimum on the compact interval I.

$$(\text{Recall} \quad M \stackrel{\text{let}}{=} \sup_{x \in \mathcal{I}} f(x) \quad \Rightarrow \quad f(x) \leq M \quad \forall x \in \mathcal{I}$$

Thus if  $\exists \overline{x} \in I$  s.t.  $f(\overline{x}) = M$ , then M becomes the maximum of f(x) on I)

Pf. Since f(x) is continuous on a compact interval I,

f(x) is bounded on I (by the Boundedness Theorem)

$$\dots$$
  $M = \sup_{x \in \mathcal{I}} f(x)$  exists (by the Completeness Property for sets)

Then by the definition of the supremum,  $f(x) \leq M \quad \forall x \in I$ 

We have to show that  $\exists \overline{x} \in I \text{ s.t. } f(\overline{x}) = M$ 

To do this, for each integer n > 0, we can choose a point  $x_n \in I$  s.t.

This is possible, since  $M - \frac{1}{n}$  is not an upper bound for f(x) on I

By the SCT,  $\{x_n\}$  has a convergent subsequence  $\{x_{n_i}\}$  converging to a point of  $\ I$ :

$$x_{n_i} \rightarrow \overline{x}, \quad \overline{x} \in I$$

By the Squeeze theorem, we now have

$$\underbrace{M - \frac{1}{n_i}}_{M} \leq \underbrace{f(x_{n_i})}_{M} \leq \underbrace{M}_{M}$$

This shows

$$\lim_{i \to \infty} f(x_{n_i}) = M \qquad --- (*)$$

On the other hand, since f(x) is contiat  $\overline{x} \in I$  &  $x_{n_i} \to \overline{x} \ (as \ i \to \infty),$ 

$$\lim_{i \to \infty} f(x_{n_i}) = f(\overline{x}) \qquad ---(**) \quad \text{(by the Sequential Continuity Theorem)}$$

$$(*) \& (**) \Rightarrow f(\overline{x}) = M.$$

To see that f(x) also attains its minimum on I, we apply the above to -f(x)

Note that -f(x) is continuous on the compact interval I

the above 
$$\Rightarrow$$
  $-f(x)$  has a maximum point  $\underline{x} \in I$   $\Rightarrow$   $f(x)$  has a minimum point  $\underline{x} \in I$ 

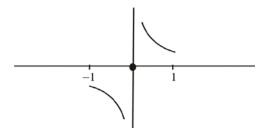

#### Remark.

(i) The conclusion in the Max-Min theorem would be false if "compact" were omitted; for example,

$$f(x) = x$$
 has no max & no min on  $(0,1)$  has no max on  $[0,\infty)$ 

(ii) The conclusion in the Max-Min theorem would be false if "continuity" were omitted; for example,

$$f(x) = \begin{cases} 1/x & x \neq 0 \\ 0 & x = 0 \end{cases} \quad \forall x \in \underbrace{[-1,1]}_{\text{cpt interval}}$$

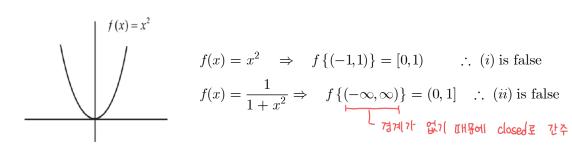

Obviously f(x) is discontinuous at 0, and it has no max or min on [-1,1]

#### 13.4 The mapping view point (about conti functions)

Q: Suppose f is continuous. Is it true that

- (i) open interval  $\stackrel{?}{\rightarrow}$  open interval
- (ii) closed interval  $\stackrel{?}{\rightarrow}$  closed interval
- (iii) bounded interval  $\stackrel{?}{\rightarrow}$  bounded interval
- (iv) compact interval  $\stackrel{?}{ o}$  compact interval True
- (v) interval  $\stackrel{?}{\rightarrow}$  interval both (EX: degenerate interval)

$$f(x) = \tan x$$
  $(x \in (-\pi/2, \pi/2))$   $\Rightarrow$   $f\{(-\pi/2, \pi/2)\} = (-\infty, \infty)$   $\therefore$  (iii) is false

$$f(x) \equiv 1 \ (\forall x \in (-\infty, \infty)) \Rightarrow f \{\text{any interval}\} = \{1\} (\text{single point})$$

Note: IVT (사이값 정리): continuous fct maps interval  $\rightarrow$  an interval or a single point

## (Ex: Prove this)

 $\therefore$  (v) is true if we regard single point as an (trivial)interval

Expect: any connected set in  $\mathbb{R}$  = an interval or single point (trivial interval)

(Easy to expect)

Thus, continuous function maps "connected sets" → "connected sets"

Remark.

$$f(x) = \begin{cases} 1 & \text{if } x \ge 0 \\ 0 & \text{if } x < 0 \end{cases} \text{ (unit step function)} \quad \Rightarrow f\left\{[-1, 1]\right\} = \{0, 1\} \text{ (two points)}$$

This example shows that if f is discontinuous, then the image of an interval under the map f need not be an interval.

The next theorem shows that (iv) is true.

#### Theorem Continuity Mapping Theorem

If f(x) is defined and continuous on the compact interval I, then f(I) is a compact interval; that is, the continuous image of a compact interval is a compact interval.

Pf. By the Max-Min theorem,  $\exists \ \underline{x}, \overline{x} \in I \ s.t.$ 

$$f(\underline{x}) = m = \inf_{x \in I} f(x),$$
  $f(\overline{x}) = M = \sup_{x \in I} f(x)$ 

We shall prove f(I) = [m, M]

$$f(I) \subset [m, M]$$
 is easy  $(: x_0 \in I \Rightarrow m \le f(x_0) \le M \Rightarrow f(x_0) \in [m, M])$ 

To prove  $f(I) \supset [m, M]$ , we must show that

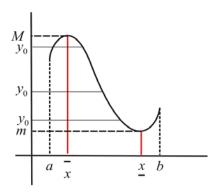

$$y_0 \in [m, M] \implies \exists x_0 \in I \text{ s.t. } y_0 = f(x_0)$$

Note that

$$y_0 \in [m, M] \iff f(\underline{x}) \le y_0 \le f(\overline{x}), \text{ where } \underline{x}, \overline{x} \in \mathcal{I}$$

Since f is conti on I, f is conti on  $[\underline{x}, \overline{x}]$  if  $\underline{x} < \overline{x}$  or on  $[\overline{x}, \underline{x}]$  if  $\overline{x} < \underline{x}$ 

 $\overset{\mathrm{IVT}}{\Rightarrow} \ \exists \ x_0 \ \ \mathrm{between} \ \ \underline{x} \ \ \mathrm{and} \ \ \overline{x} \ \ (\therefore x_0 \in \mathrm{I}) \ \ \mathrm{s.t.} \ \ y_0 = f(x_0) \, . \ \ \mathrm{Thus} \ \mathrm{we} \ \mathrm{are} \ \mathrm{done}$ 

Often useful to remember:

$$f: \text{conti on } [a,b] \quad \Rightarrow \quad f\{[a,b]\} = [m,M],$$

where 
$$m = \min_{x \in [a,b]} f(x) (= \inf_{x \in [a,b]} f(x)), \quad M = \max_{x \in [a,b]} f(x) (= \sup_{x \in [a,b]} f(x))$$

#### A comment on the IVT:

A subset I of  $\mathbb{R}$  is called an *interval* if whenever  $a < c < b \& a, b \in I$ , then  $c \in I$ Every interval is one of the following forms:

$$(a,b)$$
,  $(a,b]$ ,  $[a,b)$ ,  $[a,b]$  (where  $a < b$ ),  $(a,\infty)$ ,  $[a,\infty)$ ,  $(-\infty,b)$ ,  $(-\infty,b]$   
Singleton sets are often regarded as *degenerate* intervals

Notice that if  $I_1$  and  $I_2$  are intervals with  $I_1 \cap I_2 \neq \emptyset$  then  $I_1 \cup I_2$  is an interval.

Ex. Show that if f is continuous on an interval I, then f(I) is an interval

Pf. Notice that IVT can be stated as follows:

Suppose that f is continuous on an interval I, and  $a,b \in I$  with a < b, and that f(a) < k < f(b)Then  $a < \exists c < b$  such that f(c) = k ---  $\spadesuit$ 

To show that f(I) is an interval, we have to show that whenever r < k < s with  $r, s \in f(I)$ , then  $k \in f(I)$  Obviously,  $\exists a, b \in I$  s.t. f(a) = r, f(b) = s. May assume a < b That is,  $\exists a, b \in I$  with a < b such that f(a) < k < f(b)

By IVT  $[= \spadesuit]$ ,  $\exists c \in (a,b) \subset I$  s.t. f(c) = k --- this is what we wanted

Ex [optional].

Show that if f is continuous and strictly monotone on an **open** interval I, then f(I) is an **open** interval.

Hint:

- I: an open interval and  $x \in I \Rightarrow \exists a, b \in I \text{ with } a < x < b$
- ••  $\forall x \in I[= \text{ an interval}], \exists a, b \in I \text{ with } a < x < b \Rightarrow I = \text{ open interval}$

Pf. If I is an open interval and  $x \in I$ , then  $\exists a,b \in I$  with a < x < b

Hence

either  $f(x) \in (f(a), f(b)) \subset f(I)$  or  $f(x) \in (f(b), f(a)) \subset f(I)$  [ $\leftarrow f$  is strictly monotone] This shows that f(I) is an open interval by  $\bullet \bullet$ 

각 '점'에서 조금의 변화가 있을 시, 결과 역시 조금만 변화다는 것이다. 하나지만, Uniformly Continuous 하다는 끊 결과가 변하는 정도가 절에 위치와 상관이 없다.

### 13.5 Uniform continuity

Uniform continuity is stronger than continuity

- Continuity is a local property সুলা মহ এই
- Uniform continuity is a global property, formulated only for a function on an interval; "uniform continuity at a point" makes no sense

**Def.** We say that f is uniformly conti on the interval I (on the set  $E(\neq \emptyset) \subset \mathbb{R}$ ) if:

given  $\varepsilon > 0$ ,  $\exists \delta > 0$  (depending only on  $\varepsilon$ ) such that

$$f(x') \underset{\xi}{\approx} f(x'')$$
 for  $x' \underset{\xi}{\approx} x''$ ,  $x', x'' \in I$  (  $E$  )

의의 ٤>0을 주면,
 오로지 ٤에만 영향을 받는 8가
 존재한다.

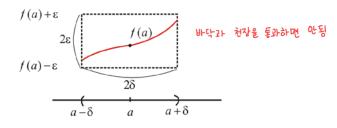

여기서 임의의 두 정 x'과 x"의 거리가 | X'-x"| < δ 하다면, | f(x') - f(x'')| < ε 가 설립한다.

Recall: f is continuous on the interval I ( $\stackrel{def}{\Leftrightarrow}$  f is continuous at every point  $a \in I$  )

 $\Leftrightarrow$  Given  $a \in I$  and given  $\varepsilon > 0$ ,  $\exists \delta = \delta(a, \varepsilon) > 0$  (may depending on  $\varepsilon \& a$ ) s.t.

$$f(x) \underset{\varepsilon}{\approx} f(a)$$
 for  $x \underset{\delta}{\approx} a$ ,  $x \overset{\text{dist}}{\leqslant} I$ 

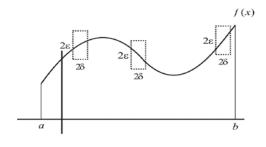

(점을 고정할 때 마다 연속이라는 것을 의미함; 점을 먼저 고정하고 조사함)

Meaning of the (pointwise) continuity: The curve y = f(x) does <u>not touch</u> the <u>top</u> or <u>bottom</u> of the rectangle  $(= 2\varepsilon \times 2\delta)$  which is centered at f(a)

주의:  $\delta$ (밑변의 길이)는  $\varepsilon$ (세로의 길이) 뿐만 아니라 점 a의 위치에 따라 변할 수 있다 ※ 세로의 길이  $(2\varepsilon>0)$ 가 주어졌을때, 곡선의 기울기의 절대값이 큰 부분일수록 위 조건을 만족하는 직사각형의 밑변의 길이  $(2\delta)$ 는 작다

(Rough) Meaning of the the uniform continuity: 점에 영향을 받지 않는 밑변의 길이 [즉, 세로의 길이에만 영향을 받는 직사각형]가 존재한다

f(x) is uniformly continuous on [a, b]

Expect f(x) is not uniformly conti

• 
$$f$$
 is uniformly contion  $I \Leftrightarrow \sup_{\substack{|x'-x''|<\delta\\x',x''\in \mathbf{I}}} \left|f(x')-f(x'')\right| \to 0 \quad \text{as} \quad \delta \to 0$ 

• 
$$f$$
 is contion I  $\Leftrightarrow$  For each  $a \in I$ ,  $\sup_{\substack{|x-a| < \delta \\ x \in I}} |f(x) - f(a)| \to 0$  as  $\delta \to 0$ 

Exa 1.  $f(x) = x^2$  is uniformly conti on [-a, a], a > 0.

Pf. Let  $\varepsilon > 0$  be given. Then for  $x', x'' \in [-a, a]$ ,

$$|f(x') - f(x'')| = |x'^2 - x''^2| = |x' - x''| |x' + x''|$$

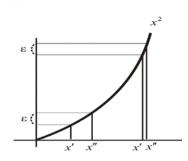

$$\leq |x' - x''| (|x'| + |x''|)$$

$$\leq 2a |x' - x''| < \varepsilon \quad \text{if} \quad |x' - x''| < \frac{\varepsilon}{2a} (= \delta)$$

That is,  $f(x') \approx f(x'')$  for  $x' \approx \frac{1}{\varepsilon} \sum_{i=1}^{\infty} x'', \quad x', x'' \in [-a, a]$ 

$$\therefore f(x) = x^2 \text{ is uniformly conti on } [-a, a].$$

Exa 2. Show that  $f(x) = x^2$  is not uniformly conti on  $[0,\infty)$ 

প্রথম Pf. Suppose to the contrary that 
$$f$$
 is uniformly conti on  $[0,\infty)$ . Then

$$\exists \ \delta > 0 \text{ s.t. } |x'^2 - x''^2| < 1 \text{ if } |x' - x''| < \delta, \ x', x'' \in [0, \infty)$$

# Archimedian Property

By the A.P.,  $\exists$  a natural number n so large that  $n\delta > 1$ .

Set 
$$x' = n$$
 and  $x'' = n + \frac{\delta}{2}$ . Then  $|x' - x''| = \frac{\delta}{2} < \delta$  but 
$$1 > |x'^2 - x''^2| = \left|n^2 - (n + \frac{\delta}{2})^2\right| = n\delta + \frac{\delta^2}{4} > n\delta > 1, \text{ is a contradiction}$$

**Remember**: f is uniformly conti on  $I \Rightarrow f$  is conti on I.

### **X Standard examples of uniformly continuous functions**

1. Lipschitz functions (often called Lipschitz continuous functions)

Suppose  $f: I \to \mathbb{R}$  is a Lipschitz function, that is,

$$\exists M > 0 \text{ s.t. } |f(x) - f(y)| \le M|x - y| \text{ for all } x, y \in I$$

Then f is uniformly continuous on I

Pf. Given  $\varepsilon > 0$ ,

$$|f(x) - f(y)| \le M|x - y| < \varepsilon$$
 if  $|x - y| < \underbrace{\frac{\varepsilon}{M}}_{\text{(depends only on }\varepsilon)}$  and  $x, y \in I$ 

→ 구간 I 에 있는 두 정 X, y의 거리와
f(X)와 f(y)의 거리가 쓩상 |f(X)-f(y)| ≤ M|X-y|를
만확합 때, f를 Lipschitz Function 이라고 하다.

i.e., 
$$f(x) \underset{\varepsilon}{\approx} f(y)$$
 for  $x \underset{\varepsilon}{\approx} y$ ,  $x, y \in I$ 

Therefore, f is uniformly continuous on I

Examples: ax (a : real),  $\sin x$ ,  $\cos x$ ,  $\sin^2 x$ ,  $\cos^2 x$ ,  $\frac{1}{1+x^2}$  are Lipschitz fcts

For instance, if  $f(x) = \frac{1}{1+x^2}$ , then  $\exists \xi$  between x and y such that

$$f(x) - f(y) = f'(\xi)(x - y) \quad \text{(by MVT)}$$

$$= -\frac{2\xi}{(1 + \xi^2)^2}(x - y)$$

$$\therefore \quad |f(x)-f(y)| = \frac{2\mid\xi\mid}{1+\xi^2} \cdot \frac{1}{1+\xi^2} \mid x-y\mid \leq 1 \cdot 1 \cdot \mid x-y\mid \quad \text{ for all } x,y \in \mathbb{R}$$

Remark: f is diffion I and  $|f'(x)| \le M \ \forall x \in I \Rightarrow f$  is Lipschitz on I

Ex (easy). Give a geometric interpretation of Lipschitz function

#### Remark.

 $f: I \to \mathbb{R}$  is such that

$$\exists M > 0: |f(x) - f(y)| \le M |x - y|^{\alpha} (0 < \alpha < 1)$$

 $\Rightarrow$  f is uniformly conti on I

 $f: I \to \mathbb{R}$  is such that

$$\exists M > 0: |f(x) - f(y)| \le M|x - y|^{\alpha} (\alpha > 1)$$

 $\Rightarrow$  f is constant on I

Pf. ① Given  $\varepsilon > 0$ ,

$$|f(x) - f(y)| \le M |x - y|^{\alpha} < \varepsilon \quad \text{if} \quad |x - y| < \underbrace{\left(\frac{\varepsilon}{M}\right)^{1/\alpha}}_{\equiv \delta \text{(depends only on } \varepsilon)} \& x, y \in \mathbf{I}$$

$$f(x) \approx f(y)$$
 for  $x \approx y$ ,  $x, y \in I$ 

② Suppose  $\alpha > 1$  and let  $y \in I$  be fixed. Then the hypo  $\Rightarrow$ 

$$\left| \frac{f(x) - f(y)}{x - y} \right| \le M |x - y|^{\alpha - 1} \quad \forall x, y \in I \text{ with } x \ne y$$

$$\therefore \lim_{x \to y} \left| \frac{f(x) - f(y)}{x - y} \right| \le M \lim_{x \to y} |x - y|^{\alpha - 1} = 0 \quad (\because \alpha > 1)$$

$$LHS = \left| \lim_{x \to y} \frac{f(x) - f(y)}{x - y} \right| \quad \text{(by the continuity of } | \quad |)$$

i.e., 
$$f'(y) = 0 \quad \forall y \in I$$
.  $\therefore f = \text{constant on } I$ 

Note. In general, f is Lipschitz on  $I \not \Rightarrow f$  is diff on I

For example, f(x) = |x| is Lipschitz on [-1, 1] (easy to check), but clearly

the function  $\mid x \mid$  is not diff at the point  $\ 0$ .

Ex. Already seen that if f is diff & has bounded derivative on I, then f is Lipschitz on I. However, in general, f is diff on  $I \not \Rightarrow f$  is Lipschitz on I: Give such an example

Ex. Prove that  $f(x) = \sqrt{x}$  is uniformly continuous on  $[0, \infty)$ .

# 2. Uniform Continuity Theorem ( = UCT)

If I is a compact interval, then

f is conti on I  $\Rightarrow$  f is uniformly conti on I

Pf. Suppose to the contrary that f is not uniformly continuous on I. 경론부정

$$\forall \delta > 0, \quad \exists \text{ a pair of points } x', x'' \in I \text{ s.t.}$$

$$|x' - x''| < \delta, \quad \text{but } |f(x') - f(x'')| \ge \varepsilon_0 \quad \text{for some } \varepsilon_0 > 0$$

X'와 X"의 차이가 용부다 작계 장을 수 있는데도 |f(x')-f(x")| > 60 인 경우7+ 있다 하다

In particular, the above property holds for  $\ \delta=\frac{1}{2},\frac{1}{3},\frac{1}{4},\cdots,\frac{1}{n},\cdots$ 

In other words, for every positive integer  $n \geq 2$ ,  $\exists$  a pair of points  $x'_n, x''_n \in I$  s.t.

(1) 
$$|x'_n - x''_n| < \frac{1}{n}$$
, but

(2) 
$$|f(x_n') - f(x_n'')| \ge \varepsilon_0$$

Since I is compact, the Sequential Compactness Theorem says the sequence  $\{x'_n\}$  has a convergent subsequence  $\{x'_{n_i}\}$  converging to a point  $c \in I$ :

(3) 
$$\lim_{i \to \infty} x'_{n_i} = c, \quad c \in \mathcal{I}$$

Also, (4) 
$$\lim_{i \to \infty} (x'_{n_i} - x''_{n_i}) = 0$$
 (by (1))

Then we also have

$$\lim_{i \to \infty} x_{n_i}'' = c \quad \left( :: \quad x_{n_i}'' = (x_{n_i}'' - x_{n_i}') + x_{n_i}' \to 0 + c = c \right)$$

We now show f(x) is not continuous at  $c \in I$ .

If f were continuous at c, then the Sequential Continuity Theorem, together with (3) & (4), would imply that

$$f(x'_{n_i}) - f(x''_{n_i}) \rightarrow f(c) - f(c) = 0$$
 as  $i \rightarrow \infty$ 

Therefore

$$\left| \frac{\left| f(x'_{n_i}) - f(x''_{n_i}) \right| < \varepsilon_0}{7$$
는정과 워버팅 for  $i \gg 1$ , which contradicts (2).

Thus f(x) is not continuous at c. This completes the proof by contraposition

#### Remark.

# Theorem (A useful criterion for non-uniform continuity)

Let  $\,f: {
m I} 
ightarrow {\Bbb R}\,\,$  be a function. Then

f is not uniformly conti on  $\ensuremath{\mathrm{I}}$  if and only if

 $\exists \ \varepsilon_0 > 0 \ \ \ {\rm and} \ \ a \ \ {\rm pair} \ \ {\rm of sequences} \ \ \left\{x_n'\right\} \ \ {\rm and} \ \ \left\{x_n''\right\} \ \ {\rm in} \ \ {\rm I} \ \ {\rm such that}$ 

$$x'_n - x''_n \to 0$$
 as  $n \to \infty$ , but  $|f(x'_n) - f(x''_n)| \ge \varepsilon_0$  for every  $n$ 

Pf.  $(\Rightarrow)$  Already seen

 $(\Leftarrow)$  Assume that the latter holds. Then, by the first part, given  $\delta > 0$ ,

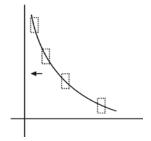

$$x'_n, x''_n \in I$$
 and  $x'_n \approx x''_n$  for  $n \gg 1$ , say for  $n \geq N$  (In particular,  $x'_N, x''_N \in I$  and  $x'_N \approx x''_N$ )

Consequently,

$$\forall \delta > 0$$
,  $\exists$  a pair of points  $x'_N, x''_N \in I$  such that  $x'_N \approx x''_N$ , but  $|f(x'_N) - f(x''_N)| \ge \varepsilon_0$  (for some  $\varepsilon_0 > 0$ )

 $\therefore$  f is not uniformly conti on I

Exa A.  $f(x) = \frac{1}{x}$  is conti (already seen) but not uniformly conti on  $(0, \infty)$ 

Pf. Choose the sequences  $\{x_n'\}$  and  $\{x_n''\}$  in  $(0,\infty)$  as

$$x'_n = \frac{1}{n}$$
 and  $x''_n = \frac{1}{n+1}$   $(n = 1, 2, \dots)$ 

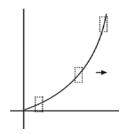

Then 
$$x'_n - x''_n = \frac{1}{n} - \frac{1}{n+1} = \frac{1}{n(n+1)} \to 0$$
 as  $n \to \infty$ 

But

$$|f(x'_n) - f(x''_n)| = |n - (n+1)| = 1 \ge \varepsilon_0 (\equiv 1/2)$$
 for every  $n$ 

 $\therefore$  f is not uniformly conti on  $(0,\infty)$ 

Exa B.  $f(x)=x^2$  is not uniformly conti on  $[0,\infty)$ 

First pf. An indirected proof was previously given in Exa 2

**Second pf.** Let 
$$x'_n = n + \frac{1}{n}$$
,  $x''_n = n$   $(n = 1, 2, \cdots)$ 

Then  $\left\{x_n'\right\}$  and  $\left\{x_n''\right\}$  are two sequences in  $[0,\infty)$  such that

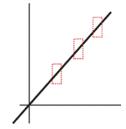

$$x_n' - x_n'' = \frac{1}{n} \to 0$$
 as  $n \to \infty$ ,

but

$$|f(x'_n) - f(x''_n)| = (n + \frac{1}{n})^2 - n^2 = 2 + \frac{1}{n^2} \ge 2 (\equiv \varepsilon_0)$$
 for every  $n$ 

 $\therefore \quad f \quad \text{is not uniformly conti on} \quad [0,\infty)$ 

Exa C. f(x) = x is uniformly conti on  $(-\infty, \infty)$ 

Pf. 
$$|f(x) - f(y)| = |x - y|$$
 for all  $x, y \in (-\infty, \infty)$ 

Thus, given  $\varepsilon > 0$ ,

$$|f(x) - f(y)| = |x - y| < \varepsilon$$
 whenever  $|x - y| < \varepsilon (\equiv \delta)$ 

f is uniformly conti on  $(-\infty, \infty)$ 

In fact, f is Lipschitz continuous on  $(-\infty, \infty)$ 

Exa D.  $f(x) = x^2$  is uniformly conti on [0, b], where b > 0

Pf. f is conti on [0,b] & [0,b] is a compact interval  $\stackrel{\text{UCT}}{\Rightarrow} f$  is uniformly conti on [0,b]

"Another pf"

$$|f(x) - f(y)| = |x^{2} - y^{2}| = |x - y| |x + y|$$

$$\leq |x - y| (|x| + |y|)$$

$$\leq 2b |x - y| \quad \forall x, y \in [0, b]$$

 $\therefore$  f is Lipschitz conti on [0, b]

 $\therefore$  f is uniformly conti on [0, b]

**Remark.**  $f(x) = x^2$  is uniformly conti on (0, b), where b > 0

Pf 1. f is uniformly conti on [0, b] by UCT

 $\therefore$  f is uniformly conti on the smaller interval (0, b)

Pf 2.

$$| f(x) - f(y) | = | x^2 - y^2 | = | x - y | | x + y |$$
  
 $\leq | x - y | (| x | + | y |)$   
 $\leq 2b | x - y | \forall x, y \in (0, b)$ 

 $\therefore$  f is Lipschitz conti on (0, b)

 $\therefore$  f is uniformly conti on (0, b)

Exa E.  $f(x) = \sqrt{x}$  is uniformly conti on  $[1, \infty)$ 

Pf. 
$$|f(x) - f(y)| = |\sqrt{x} - \sqrt{y}| = \frac{|x - y|}{\sqrt{x} + \sqrt{y}} \le \frac{1}{2} |x - y| \quad \forall x, y \in [1, \infty)$$

 $\therefore$  f is Lipschitz conti on  $[1, \infty)$ 

 $\therefore$  f is uniformly conti on  $[1, \infty)$ 

Exa F. Not every uniformly continuous function is Lipschitz

Sol.  $f(x) = \sqrt{x}$  is uniformly conti on [0, 2] (by UCT)

Claim: f is not Lipschitz conti on [0, 2]

Pf of Claim: Suppose f were Lipschitz conti on [0, 2]. Then

$$\exists \ M>0 \ \ \text{such that} \ \mid f(x)-f(y)\mid \leq M\mid x-y\mid \quad \ \forall x,y\in [0,2]$$

In particular (by taking y = 0), we have

$$|f(x)| \le M |x| \quad \forall x \in [0, 2]$$

$$\therefore \frac{|f(x)|}{|x|} \le M \quad \forall x \in (0,2]$$

Recall that M is independent of  $x \in (0,2]$ 

Letting 
$$x \to 0^+ \Rightarrow \lim_{x \to 0^+} \frac{|f(x)|}{|x|} \le M$$

This contradicts the fact that

$$\frac{\mid f(x) \mid}{\mid x \mid} = \frac{\sqrt{x}}{\mid x \mid} = \frac{1}{\sqrt{x}} \to \infty \text{ Mas } x \to 0^+$$

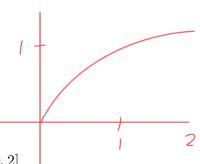

Therefore, f is not Lipschitz conti on [0, 2]

**Exa**. Show that  $f(x) = x \sin \frac{1}{x}$  is u.c. on (0,1)

Pf. 
$$F(x) \stackrel{\text{def}}{=} \begin{cases} x \sin \frac{1}{x} & x \neq 0 \\ 0 & x = 0 \end{cases}$$

It is obvious that  $\lim_{x\to 0} F(x) = 0 = F(0)$ 

It follows that F(x) is continuous  $\forall x \in (-\infty, \infty)$ 

In particular, F(x) is conti on the compact interval [0, 1]

Thus F(x) is u.c. on [0,1] (by UCT), and so F(x) is u.c. on (0,1)

But, since  $F(x) = x \sin \frac{1}{x} = f(x)$  on (0, 1), f(x) is u.c. on (0, 1)

**Remark.** Assume f is continuous on (a, b).

If, in addition,  $\lim_{x\to a^+} f(x)$  and  $\lim_{x\to b^-} f(x)$  both exist, then f is uniformly continuous on (a,b)

**Question.** f is **conti & bounded** on an interval  $I \stackrel{?}{\Rightarrow} f$  is **u.c.** on I

Ans

Yes if I is any compact interval (by UCT). In fact, in that case, the boundedness of f on I is not necessary (automatically satisfied by Boundedness theorem) but no in general if I is *not* a compact interval.

For example,  $f(x) \stackrel{\text{let}}{=} \sin \frac{1}{x}$  on the open interval  $(0, \infty)$ 

Then f(x) is conti & bounded (by 1) on  $(0, \infty)$ 

However, f(x) is not u.c. on  $(0,\infty)$  (roughly) because it is too oscillates near 0

(Draw the picture of f(x))

To give a rigorous pf, take  $\ x_n'=rac{1}{n\pi}, \quad x_n''=rac{1}{2n\pi+\pi/2} \quad (n=1,2,\cdots).$ 

Then  $\{x_n'\}$  and  $\{x_n''\}$  are two sequences in  $(0,\infty)$  such that

$$x_n' - x_n'' \to 0$$
 as  $n \to \infty$ ,

But  $|f(x'_n) - f(x''_n)| = 1 \ge \frac{1}{2} (\equiv \varepsilon_0)$  for every n

 $\therefore$  f(x) is not u.c. on  $(0,\infty)$ 

Home-Study problems.

1. Find an example of a continuous function  $f: \mathbb{R} \to [-1,1]$  such that f is **not** uniformly continuous.

Answer.  $f(x) := \cos(x^2)$  [or  $f(x) := \sin(x^2)$ ] is the desired example --- verify this

2. Let  $f(x) = 2\sqrt{x} - 3\sin x + \ln(x^2 + 1)$ ,  $I = [1, \infty)$ Is the function f uniformly continuous on I?

**Ex.** Show that  $f(x) = \sqrt{x}$  is uniformly conti on  $[0, \infty)$ .

**Pf**. We know that

 $f(x) = \sqrt{x}$  is uniformly conti on [0, 1] (by UCT)

and

 $f(x) = \sqrt{x}$  is uniformly conti on  $[1, \infty)$ .  $[\leftarrow f(x) = \sqrt{x}$  is Lipschitz conti on  $[1, \infty)$ 

Hence, given any  $\varepsilon > 0$ , there is a  $\delta_1 = \delta_1(\varepsilon) > 0$  such that

$$x, y \in [0, 1], |x - y| < \delta_1 \implies |f(x) - f(y)| < \varepsilon$$

There is also a  $\delta_2 = \delta_2(\varepsilon) > 0$  such that

$$x, y \in [1, \infty), |x - y| < \delta_2 \implies |f(x) - f(y)| < \varepsilon.$$

Now define  $\delta := \min \{ \delta_1(\varepsilon), \delta_2(\varepsilon) \}$  and let  $x, y \in [0, \infty)$  be such that  $|x - y| < \delta$ .

If both  $\ x \ \& \ y \in [0,1]$  , or if both  $\ x \ \& \ y \in [1,\infty)$  , then it is clear that  $\ \left| f(x) - f(y) \right| < \varepsilon$ 

For the remaining case, we may suppose without essential loss of generality that x < 1 < y. Then

$$|1-x|<|y-x|<\delta\leq\delta_1$$
 and so  $|f(1)-f(x)|<\varepsilon$ 

Similarly,

$$\mid y-1\mid <\mid y-x\mid <\delta \leq \delta_{2} \ \ \text{and so} \ \ \left|f(y)-f(1)\right|<\varepsilon$$

Therefore,

$$|f(x) - f(y)| \le |f(x) - f(1)| + |f(1) - f(y)| < \varepsilon + \varepsilon = 2\varepsilon$$

**Another (lucky) pf.** For any  $x, y \in [0, \infty)$ , we have

$$|f(x) - f(y)|^2 = |\sqrt{x} - \sqrt{y}|^2 \le |\sqrt{x} - \sqrt{y}||\sqrt{x} + \sqrt{y}| = |x - y|$$
  
$$\therefore |f(x) - f(y)| \le |x - y|^{1/2}$$

Let  $\varepsilon > 0$  be given. Take  $\delta = \varepsilon^2$ . Then

$$|x-y| < \delta \quad \Rightarrow \quad |f(x) - f(y)| \le |x-y|^{1/2} < \sqrt{\delta} = \varepsilon$$

#### Proposition [A criterion for non-uniform continuity: essentially proved earlier]

--- Remember the result ---

Let  $f: I \subset \mathbb{R} \to \mathbb{R}$  be the function. Then

$$f$$
 is uniformly continuous on  $I$   $\Leftrightarrow$  
$$\begin{cases} \forall \text{ two sequences } \{u_n\} \& \{v_n\} \text{ such that} \\ \lim_{n \to \infty} (u_n - v_n) = 0 \Rightarrow \lim_{n \to \infty} [f(u_n) - f(v_n)] = 0 \end{cases}$$

Pf.  $(\Rightarrow)$  Let  $\varepsilon > 0$ . Since f is u.c. on I,  $\exists \delta > 0$  such that

$$x, y \in I \& |x - y| < \delta \implies |f(x) - f(y)| < \varepsilon --- \blacksquare$$

Suppose  $\{u_n\}$  &  $\{v_n\}$  are two sequences in I such that  $\lim(u_n - v_n) = 0$ 

$$\Rightarrow \exists N \big[ = N(\delta) = N(\varepsilon) \big] \in \mathbb{N} \text{ such that } |u_n - v_n| < \delta \text{ for } \forall n \ge N$$

$$\therefore |f(u_n) - f(v_n)| < \varepsilon \text{ for every } n \ge N \quad [\leftarrow \blacksquare]$$

Therefore,  $\lim_{n \to \infty} [f(u_n) - f(v_n)] = 0$ 

 $(\Leftarrow)$  Suppose f is not uniformly continuous on I.

$$\Rightarrow \ \exists \varepsilon_0 > 0 \ \text{ such that } \ \forall \delta > 0, \ \exists x_\delta, y_\delta \in I \ \text{ for which } \ |x_\delta - y_\delta| < \delta \ \& \ |f(x_\delta) - f(y_\delta)| \ge \varepsilon_0$$

Set 
$$\delta = 1 \implies \exists x_1, y_1 \in I$$
 for which  $|x_1 - y_1| < 1 \& |f(x_1) - f(y_1)| \ge \varepsilon_0$ 

Set 
$$\delta = 1/2 \implies \exists x_2, y_2 \in I$$
 for which  $|x_2 - y_2| < 1/2$  &  $|f(x_2) - f(y_2)| \ge \varepsilon_0$ 

In general, set  $\delta = 1/n \implies \exists x_n, y_n \in I$  for which  $|x_n - y_n| < 1/n \& |f(x_n) - f(y_n)| \ge \varepsilon_0$ 

Consequently, we have two sequences  $\{x_n\}$  &  $\{y_n\}$  in I s.t.

$$(x_n - y_n) \to 0$$
 but  $(f(x_n) - f(y_n)) \not\to 0$  as  $n \to \infty$
